

EARLY PREVIEW — FOR TESTERS & INVESTORS

Ridesharing that shows its work.

RideShare Genesis is a human-centred ridesharing platform where every match comes with a full, plain-language explanation — Decision DNA — instead of a score you're asked to trust blindly.

● V1 built, tested, and live now on Cloudflare's edge

EXHIBIT A — LIVE MATCH EXPLANATION

92/100 MATCH

01 THE PROBLEM

Riders and drivers are asked to trust a number they can't see.

Every matching platform scores you against someone else. Almost none show their work — and in markets where ridesharing is still informal and trust is earned trip by trip, that gap matters more, not less.

OPACITY

Black-box scores breed suspicion. When a rider or driver can't see why a match was made, every bad experience reads as the algorithm being unfair — not just unlucky.

SAFETY

Safety is bolted on, not built in. Most platforms treat incident reporting as a support ticket, not a first-class, always-available feature with its own audit trail.

PAYMENTS

One payment rail doesn't fit every rider. Card-only checkouts quietly exclude people who move money by mobile wallet, or who simply prefer to settle in cash with a driver they've just met.

02 THE PRODUCT

A complete ride, end to end — screenshotted from the running app.

Nothing below is a mockup. Every screen is captured from Genesis V1 running against its own API, seeded with a real Nairobi journey.

WELCOME

Human-centred principles, up front

BOOKING

A visible state machine, not a spinner

Requested → Matched → Confirmed → In progress → Completed, with mobile money, card,

MESSAGING

Rider and driver, talking directly

The four commitments the product is designed around, not buried in a terms page.

wallet, or cash at checkout.

A live thread scoped to the booking, so coordinating pickup never leaves the app.

Decision DNA · Why this match

Genesis rated this match 92/100. The strongest factor was proximity (0.3 km average origin/destination gap); the weakest was reliability (based on driver trip-completion history). This score is a transparent weighted blend of proximity, timing, price fit, stated preferences, and driver reliability — you can see and adjust these weights in your Decision DNA settings.

Proximity (weight 40%)

0.3 km average origin/destination gap

96/100

Timing (weight 30%)

2 min apart on departure time

98/100

Matching

The explanation is the feature

Every match ships with the same breakdown investors and testers see in Exhibit A above.

03 HOW DECISION DNA WORKS

Six factors, one transparent blend, zero hidden weights.

Genesis scores every candidate match against six factors — including environmental fit, not a bolted-on afterthought — weighted per-rider. The weights are never secret — they’re the rider’s own settings, shown back to them on every match.

91/100

Westlands → JKIA, 0.3 km origin/destination gap, same departure minute. Strongest factor: proximity. Weakest: preferences — no strong signal set yet, an honest gap, not a hidden penalty.

Proximity	weight 32%	96/100
0.3 km average origin/destination gap		
Timing	weight 28%	98/100
2 minutes apart on departure time		
Price fit	weight 13%	100/100
Offer priced at KES 650 vs. a KES 700 budget		
Preferences	weight 13%	70/100
No strong preference signals set yet		
Reliability	weight 6%	80/100
Based on driver trip-completion history		
Environmental	weight 8%	75/100
Would fill 75% of a hybrid vehicle's spare capacity		

04 WHY WE'RE BUILDING THIS NAIROBI-FIRST

The design choices, not just the pitch.

These aren't slide bullets — they're already in the product, seeded here with a real Westlands → JKIA journey priced in Kenyan shillings.

PAYMENTS

Mobile money is first-class

Card, wallet, cash, and mobile money share one provider contract — mobile money isn't a bolted-on afterthought.

TRANSIT CONTEXT

Built for informal, trip-by-trip trust

Where ridesharing already runs on personal recommendation and local knowledge, an explainable match earns trust faster than a black-box score.

CURRENCY

KES-native from day one

Journeys, bookings, and payments carry their own currency field — the Nairobi pilot runs in shillings, not a retrofitted USD default.

05 TECHNICAL CREDIBILITY

Two ways to run it — one product.

A reference Node stack for self-hosting and rapid iteration, and a from-scratch Cloudflare Workers port for global-edge production — sharing the same schema, the same matching logic, the same tests.

REFERENCE IMPLEMENTATION	PRODUCTION DEPLOYMENT
Node / Express - Express API, SQLite via better-sqlite3 - Socket.IO for real-time booking chat - JWT + bcrypt auth, Docker + docker-compose - Used for local development and self-hosting	Cloudflare Workers - Hono API on Workers, D1 as the database - A Durable Object per booking for real-time chat - Frontend served as static assets, single origin - No server to patch, scales on Cloudflare's edge

38	9	4	3
AUTOMATED TESTS, GREEN	CORE DATA TABLES	PAYMENT METHODS, ONE CONTRACT	AUTHORIZATION GAPS FOUND & FIXED PRE-LAUNCH

People first. Planet always in consideration.

Every day, vehicles travel with unused seats while other people make the same journey separately. Genesis exists to close that gap — and to measure what closing it is worth, not just claim it.

SERVE THE PERSON	RESPECT THE PLANET
Convenience isn't the trade-off Sustainability shouldn't mean less accessible mobility. Genesis stays human-centred first — the environmental case is what better-utilised capacity makes possible, not a constraint riders have to accept.	One vehicle, more people served A fuller car — surfaced by Decision DNA's own environmental factor — means fewer duplicated journeys on the same road at the same time. The mechanism, not the marketing.

01 SHARE CAPACITY Use seats already going that way Rather than adding a new vehicle to the road for a trip someone else is already making.	02 REDUCE DUPLICATION Similar journeys, travelled together Where it suits both people — never at the cost of convenience or choice.	03 EFFICIENT MOBILITY Shared options, surfaced honestly Alongside driving, not hidden behind a driving-by-default assumption.
04 CLEANER VEHICLES EVs and hybrids score higher Decision DNA already weighs vehicle type; every offer carries one.	05 MEASURE THE IMPACT Estimated on every completed trip CO2e, fuel, and vehicle-km avoided — methodology shown, not asserted.	

We won't claim Genesis reduces emissions by a headline percentage until we've measured our own journeys. What's already shipped: a vehicle-occupancy-and-fuel-type factor inside Decision DNA's match score, an estimated-impact figure on every completed booking, and a platform-wide environmental tile in the admin dashboard — live in the product, not slideware.

Built and tested. Deploying now.

No vapourware bullet points — here's exactly what's shipped, what's in flight, and what's next.

● SHIPPED	Full V1 product — auth, profiles, find/offer journeys, explainable matching, bookings, payments, messaging, Safety Centre, governance audit trail, an in-app assistant.
● SHIPPED	38 automated tests across every module, plus an internal security review that found and fixed three real authorization gaps before anyone outside the team saw the code.
● SHIPPED	Live production deployment on Cloudflare Workers, D1, and Durable Objects — registration, matching, bookings, and payments all verified working against the real, running app.
● SHIPPED	Environmental impact, built in — a sixth Decision DNA factor scoring vehicle occupancy and fuel type, an estimated CO2e/fuel/vehicle-km figure on every completed booking, and a platform-wide impact tile in the admin dashboard.

● NOW	Early-bird period, 0% commission — commission plumbing is live end-to-end (every payment records its own rate, so history never gets rewritten), held at 0% while we seed the first ~500-user cohort before turning it on.
● NEXT	Real geocoding & live maps in place of manual coordinates, driver identity verification, and a licensed payment processor behind the existing provider contract.
● NEXT	Calibrated emission factors against real trip telemetry, replacing today's published per-km averages once there's enough completed-trip volume to measure against.
● NEXT	Ride Passes for repeat pairs — a discounted recurring rate once a driver/passenger repeat a route, aimed squarely at marketplace leakage (regulars settling in cash once they've found each other) — priced against real repeat-ride data, not guessed upfront.

Sized bottom-up. Priced from what's already shipped.

Illustrative planning figures built from public population and fare-benchmark assumptions, not commissioned market research — the same "show the methodology, don't assert the number" standard as the environmental estimates above.

\$750M TAM — EAST AFRICAN URBAN RIDE-HAILING & CARPOOLING, /YR	\$150M SAM — NAIROBI METRO SHARED-RIDE SPEND, /YR	\$3M SOM — YEAR-3 NAIROBI PILOT TARGET GMV, /YR	
UNIT ECONOMICS KES 650 avg fare, 10% target take rate ≈\$0.50 revenue per ride at the post-early-bird commission rate — already live end-to-end, since every payment stores its own rate at the moment it's captured.	YEAR-3 TARGET ~5,700 monthly active riders 2% penetration of the Nairobi SAM, ≈8 rides/rider/month — the milestone the pre-seed round is sized to reach, not a hockey-stick guess.	THE ASK \$250K pre-seed, 12-month runway Real geocoding & maps, driver ID verification, a licensed payment processor, and the first 5,000-rider Nairobi cohort — see "Where V1 stands today" for what's already funded and shipped.	

Methodology: Nairobi metro population ~4.8M → ~1.9M regular paid-ride commuters → ~285K addressable for app-based shared rides (SAM basis) at ~\$520/rider/year, scaled ~5x across comparable East African metros for TAM. Figures are a planning estimate for this round, to be refined with commissioned research as the Nairobi pilot generates real usage data — the same discipline applied to the environmental figures elsewhere in this deck.

Two ways in — pick yours.
